Stacie Nam

Reflection:

Since this was my first time coding with HTML/CSS without specific guidelines or instructions(except for the instruction that we have to correctly render the hifi prototype we've already created) and further advancing what I have self-learned and practiced in lab, I encountered challenges relatively early in this process. What I did in previous labs were creating vertical lists and creating buttons that would add and delete items in the list, but for this assignment I had to do more than that - I had to render the design I made which also includes some images with different layouts in each page. Creating table and inserting images in each cell helped me figure out most of the layout problems. To incorporate the opacity for the images at the bottom of the main page, I had to use both class and table tag, where I placed class tags inside the table tag, for each of the images, and then moved on to CSS to control the opacity. Absolute and relative positions in CSS when placing both texts and images were also a challenge. They work differently so I had to simulate how the images and texts would be placed relative to each other. I had to edit and change the numbers/pixels multiple times accordingly.

The client is a bakery shop that their main products are various flavors of cinnamon rolls. So I set the overall color pallette a warm beige- warm yellow-warm brown range with lighter tones that wouldn't conflict with the dark brown colored images of most of the cinnamon rolls. There are greater emphasis on the images than texts because consumers of food product usually care more about the visual quality of the image of food, whether the product would satisfy their appetite. So from the main page and the product browsing page, users can access product browsing page or product detail page by clicking the images. It is easier and more likely for users to click on the images that are appealing to them than static texts.
